Contribution Number CRD-88/89-19

August 1989

The Sea Turtle Stranding and Salvage Network (STSSN) was formally established in 1980 to collect information on and document strandings of marine turtles along the U.S. Gulf of Mexico and Atlantic coasts. The network encompasses the coastal areas of the eighteen state region from Maine through Texas, and includes portions of the U.S. Caribbean. Data are compiled through the efforts of network participants who document marine turtle strandings in their respective areas and contribute those data to the centralized STSSN data base.

This report summarizes marine turtle strandings documented through the efforts of the STSSN during the calendar year 1988. The numbers presented are considered minimum stranding figures, as they are reported strandings only, not all stranding events. Effort expended in the collection of stranding data during 1988 varied both geographically and temporally. Coverage ranged from systematic weekly (or more frequent) sampling to no sampling at all in some coastal areas.

A total of 2020 stranded marine turtles were reported during 1988. Of these, 1991 were "wild" strandings and the remaining 29 were known headstarted turtles. Headstarted turtles are hatched and raised in captivity for approximately six to twelve months before being tagged and released. Strandings of headstarted turtles are documented in Table 23, but are not included in any of the figures presented in the text or in the histograms. Strandings of headstarted turtles are excluded because they may represent an added bias if their stranding was an artifact of captive rearing and release. Reports of incidentally captured turtles and live sighting reports received through the network were archived, but are not included in this report as these records were not considered to be true strandings. True strandings are defined as turtles which wash ashore dead or alive or are found floating dead or alive (generally in a weakened condition).

Thirteen states reported strandings during the twelve month period. They are: Texas, Louisiana, Mississippi, Alabama, Florida, Georgia, South Carolina, North Carolina, Virginia, New Jersey, New York, Rhode Island, and Massachusetts. There were no stranding records received from Maryland, Delaware, Connecticut, New Hampshire, or Maine. For the U.S. Caribbean, records were received from Puerto Rico and the U.S. Virgin Islands.

Annual Comparison

Figure 1 depicts annual stranding totals for all species combined over the entire network area. Direct annual comparisons are complicated by the variation in effort between and/or within years. Network-wide, data collection efforts have been most consistent during the period 1984-1988. The 1988 stranding total of 1991 turtles is a 16% decrease from the 1987 stranding total. The 1988 total is the third highest annual total, surpassed only by strandings in 1987 and 1980, and accounts for 13.8% of all reported strandings over the nine year period 1980-1988.

State and Regional Distribution

Reported strandings during 1988 are summarized by state in Table 1 and Figure 2. Florida reported the highest number of strandings during 1988, accounting for 49% of the total (11% Florida-Gulf, 38% Florida-Atlantic). Georgia accounted for 11% of the total reported strandings, while Texas and North Carolina reported the third and fourth highest stranding frequencies, accounting for 10% each.

Regionally, 24.3% of total strandings were reported from the Gulf of Mexico (TX,LA,MS,AL,FL-Gulf), 64.0% from the southeast U.S. Atlantic (FL-Atlantic,GA,SC,NC), 11.2% from the northeast U.S. Atlantic (VA,MD,DE,NJ,NY,CT,RI,MA,NH,ME), and 0.5% from the U.S. Caribbean (PR,USVI). Stranding records are summarized on a detailed state by state basis in Tables 4-19. These tables summarize strandings by species and month (all counties combined) and by county and month (all species combined).

Network-wide, 82.1% of all reports were classified as offshore strandings and 17.9% were classified as inshore strandings. Offshore strandings are defined as strandings occurring on the ocean beaches, while inshore strandings are those occurring landward of the ocean coastline, primarily in bays and sounds. The regional distribution of inshore versus offshore strandings for 1988 (excluding the Caribbean) was as follows:

	<u>GULF</u>	<u>SOUTHEAST U.S.</u>	<u>NORTHEAST U.S.</u>
INSHORE	94 (19.4%)	146 (11.5%)	115 (51.6%)
OFFSHORE	390 (80.6%)	1128 (88.5%)	108 (48.4%)

Species Composition

Throughout the network region, loggerheads (Caretta caretta) were the most frequently stranded species making up 69.3% (1380) of the total. Kemp's ridleys (Lepidochelys kemp) were the second most frequently reported species at 10.9% (217); green turtle (Chelonia mydas) strandings comprised 9.9% (198) of the total; leatherbacks (Dermochelys coriacea) accounted for 4.0% (79) of all reports; and hawksbills (Eretmochelys imbricata) were reported least frequently making up 1.4% (27) of the total. Turtles not identified to species accounted for 4.5% (90) of all reports. Figures 3-5 depict total strandings by species for the Gulf of Mexico, southeast U.S. Atlantic, and northeast U.S. Atlantic, respectively.

Within each region (excepting the Caribbean), loggerheads were the most frequently stranded species making up 64% (307), 72% (915), and 71% (158) of the region total for the Gulf, southeast U.S. Atlantic, and northeast U.S. Atlantic, respectively. In the Gulf of Mexico, Kemp's ridleys were the second most frequently stranded species comprising 16% (76) of the total, followed by green turtles comprising 9% (45). In the southeast U.S. Atlantic, green turtles were the second most frequently stranded species accounting for 12% (146) of all reports, while Kemp's ridleys made up 10% (122) of the stranding total. In the northeast U.S. Atlantic, leatherback and Kemp's ridley strandings accounted for 17% (38) and 9% (19) of the region total, respectively.

As compared to 1987, strandings of green turtles increased 21% for all regions combined. This increase occurred only in the southeast U.S. Atlantic where reports of green turtle strandings increased from 77 in 1987 to 147 in 1988, almost a 100% increase. Green turtle strandings decreased in all other regions.

Strandings of leatherbacks, loggerheads, and hawksbills decreased 47%, 22%, and 10%, respectively, for all regions combined. The decrease in leatherback strandings occurred in the Atlantic regions with strandings dropping from 144 in 1987 to 68 in 1988, a little more than a 100% decrease. Strandings of leatherbacks in the Gulf of Mexico increased over 1987 levels. Strandings of hawksbills decreased from 13 in 1987 to 8 in 1988 in the southeast U.S. Atlantic, but increased in the Gulf of Mexico from 11 in 1987 to 15 in 1988. No hawksbills stranded in the northeast U.S. Atlantic. Fewer loggerhead strandings were reported from all regions with decreases of 19%, 23%, and 19% in the Gulf of Mexico, southeast U.S. Atlantic, and northeast U.S. Atlantic, respectively.

Strandings of Kemp's ridleys remained consistent with 1987 levels for all regions combined. However, in the southeast U.S. Atlantic, Kemp's ridley strandings more than doubled, increasing from 52 in 1987 to 122 in 1988. Strandings of Kemp's ridleys decreased from 103 to 76 in the Gulf of Mexico and from 65 to 19 in the northeast U.S. Atlantic.

Distribution by Statistical Zone

Strandings were summarized by statistical zones to examine the geographic distribution within regions. The statistical zones utilized were originally designed by the Bureau of Commercial Fisheries (now NMFS) for shrimp catch and effort data collection and have subsequently been used to define areas where Turtle Excluder devices (TEDs) are required. The actual coastal areas encompassed by each of the zones are not equal. Tables 20-22 summarize 1988 strandings by month and zone for the Gulf of Mexico, southeast U.S. Atlantic, and northeast U.S. Atlantic, respectively.

There are 23 zones in the U.S. Gulf of Mexico (Figure 6). Zones 1 through 21 are numbered consecutively along the Gulf coast from the Florida Keys to the Mexico border. Zones 24 and 25 are partial zones, shared with the southeast U.S. Atlantic region, and include the area west of longitude 80 30'. Total strandings by zone for the Gulf of Mexico are depicted in Figure 6. Strandings were approximately equally divided between the eastern Gulf (Zones 1-12, 24, 25) and the western Gulf (Zones 13-21). Sixty-seven percent (67%) of all Gulf Kemp's ridley strandings were reported from the western Gulf, with the majority of these turtles stranding in Zones 18, 19, and 20 along the Texas coast. Zone 17 was the only zone in which Kemp's ridley strandings decreased substantially, dropping from 14 in 1987 to 1 in 1988.

Thirteen statistical zones are defined by degree of latitude for the southeast U.S. Atlantic. Zones are numbered from south to north, based on the line of latitude which forms the southern boundary of the zone (Figure 7). Zones 24 and 25 are partial zones which include of the area east of longitude 80 30'. Zone 36 is also a partial zone, ending at the North Carolina/Virginia border. Figure 7 depicts total southeast U.S. strandings by statistical zone. Peak strandings were reported from Zone 30 off the northeast Florida coast and southern tip of Georgia, 22% of all southeast U.S. strandings occurred in this zone. Zone 30 has had the highest number of strandings in the network since 1984. Zones 29 and 27 off the Florida coast accounted for the second and third highest stranding frequencies, comprising 16% and 13% of the region total, respectively. Strandings in Zones 31 and 32 substantially decreased from a 1987 total of 514 to 217 in 1988. Zones 29, 30, and 31 accounted for 83% of all southeast

U.S. Kemp's ridley strandings. Kemp's ridley strandings in these zones increased from 29 in 1987 to 101 in 1988. Strandings of Kemp's ridleys in all other zones remained relatively consistent with 1987 levels.

Nine statistical zones are defined for the northeast U.S. Atlantic beginning with the Virginia portion of Zone 36 and continuing north through Zone 44 ending at the Canadian border (Figure 8). The northeast U.S. portion of Zone 36 and Zone 37 accounted for 63% of the total northeast U.S. strandings and primarily represent turtles stranding in Chesapeake Bay and along the Virginia barrier beaches. Strandings in Zones 40 and 41 represent 28 % of the total northeast U.S. strandings. Strandings in Zones 40 and 41 substantially decreased from a 1987 total of 168 to only 62 in 1988. There was a 94% decrease in the number of turtles reported cold-stunned as compared to 1987 which may account for this overall decrease in strandings. Sixty-eight percent (68%) of all northeast U.S. Kemp's ridley strandings were reported from Zones 36 and 37, with the remaining 32% being reported from Zone 41.

Systematic Sampling

Sampling in selected statistical zones was completed systematically to develop an index of mortality that can be compared spatially and temporally. For 1988, sampling was conducted either aerially or on the ground within zones 4 and 5 by the Florida Department of Natural Resources. Sampling within zones 17 through 21 was coordinated by the NMFS Southeast Fisheries Center, Galveston Laboratory. Dr. Lew Ehrhart, University of Central Florida, continued to sample via aerial survey in zones 28 and 29 with the addition of zone 30 in November 1988. The Georgia Department of Natural Resources implemented systematic sampling of zone 31 in September 1988. The South Carolina Department of Wildlife and Marine Resources continued to sample, as in the past, on a systematic basis within zone 32.

Given the systematic sampling regime within these zones and that the stranding data reported still represents minimum numbers, these data, when standardized for effort, should provide an index of total mortality. The peak in total strandings in the Gulf (zones 4, 5, 17-21) occurred in April/May (Tables 23 and 24). In South Carolina (zone 32) the peak in total strandings occurred in July/August (Table 27). Reported strandings along the Florida east coast (zones 28,29) were relatively high in all months except February (Table 25). Systematic sampling was not initiated in Georgia until September, thus a peak for zone 31 could not be determined (Table 26).

Temporal Distribution of Strandings

Table 2 summarizes 1988 strandings by state and month for all species combined. Table 3 summarizes strandings by species and month for all states combined. Figures 9-11 depict monthly stranding frequencies for 1987 and 1988 for the Gulf of Mexico, southeast U.S. Atlantic, and northeast U.S. Atlantic, respectively.

The monthly frequency distribution for Gulf of Mexico strandings is presented in Figure 9. Strandings occurred during all months, with a peak during the period April-May. Stranding frequencies in the Gulf of Mexico decreased or remained consistent with 1987 levels for all months except November when strandings increased more than 100%, from 17 in 1987 to 46 in 1988. Overall, stranding frequencies in the Gulf of Mexico followed the same general trend by month in 1988 as they did in 1987.

In the southeast U.S. Atlantic (Figure 10), strandings peaked during the summer months of May - August with a secondary peak in November. Strandings in the southeast U.S. Atlantic increased over 1987 levels in all months except May, June, and July. Total strandings in these three months decreased from 910 in 1987 to 437 in 1988.

In the northeast U.S. Atlantic (Figure 11), June was the peak stranding month accounting for 27% of all strandings within the region. Strandings in May increased from 4 in 1987 to 20 in 1988, while a decrease in strandings occurred during the period August - December. Strandings in all other months remained consistent with 1987 levels. June and July strandings are almost entirely comprised of Virginia strandings (89%), while the months of August - December represent turtles stranding in Virginia (42%), New York (21%), New Jersey (18%), Massachusetts (17%), and Rhode Island (2%).

Condition of Stranded Turtles

Of 1991 stranded turtles, 93.1% were dead, 5.8% were alive, and the conditions of the remaining 1.1% were not recorded. Of the 115 live turtles, 18% were released, 57% subsequently died, and the fates of the remaining 29 turtles (25%) are unknown. A total of 148 turtles (7.4%) were reported as necropsied. The conditions of the 1854 turtles stranded dead were reported as follows:

Fresh Dead	424 (22.9%)
Moderately Decomposed	687 (37.1%)
Severely Decomposed	559 (30.1%)
Dried Carcass	110 (5.9%)
Skeleton, Bones Only	74 (4.0%)

Carcass Anomalies

Observations (not necessarily causes of death) recorded on stranding reports specific to the individual turtle are coded as a permanent part of each stranding record. Selected carcass anomalies are summarized below. Occurrence rates reported during 1987 are given for comparison. These figures are considered minimum percent occurrences, as a report form lacking remarks does not always indicate a "clean" turtle. Used herein, "entangled" implies washed ashore (i.e. a true stranding) with the entangling materials still attached to the turtle.

	<u>1987</u>	<u>1988</u>
Boat Related Injuries (Prop or Collision)	7.3%	9.0%
Carapace Damage (Unknown Cause)	7.3%	10.4%
Plastron Damage (Unknown Cause)	1.3%	1.0%
Skull Injuries	2.4%	2.4%
Skull Missing	2.1%	3.5%
Skull & Flipper(s) Combination Missing	7.0%	7.1%
Flipper(s) Missing (Unknown Cause)	4.0%	7.3%
Flipper(s) Missing (Man Induced)	1.9%	1.2%
Partial Flipper Damage (Unknown Cause)	7.9%	8.6%
Bullet Wounds	.8%	.5%
Apparent Shark Wounds	1.2%	.7%
External Tumors	1.5%	1.3%
Apparent Deliberate Mutilation	3.3%	3.3%
Tar or Oil Impact	.6%	.4%
Cold Stun Related	3.4%	.3%
Entangled in Fishing Line	.7%	.7%
Entangled in Fishing Net	.2%	.3%
Entangled in Non-Fishing Gear Materials	.3%	.2%
Rope(s) Tied to Flippers, Neck, or Body	.6%	.7%
Fishing Line Protruding From Mouth or Cloaca (Not Entangled)	.1%	.4%
Fishing Hook in Mouth	.1%	.3%
Plastic Ingestion (Non-Fishing Gear)	3.8%*	4.7%*
Fishing Hook in Digestive Tract	.8%*	.7%*
Fishing Line in Digestive Tract	.8%*	.7%*

* Rates of occurrence of anomalies observable only upon necropsy are expressed as a percentage of turtles necropsied (N=148).

Acknowledgements

We would like to thank the state coordinators (listed on the following pages) and the hundreds of network participants who documented strandings of marine turtles during 1988. Without the efforts and dedication of these people the network would not function as effectively as it does. Larry Hansen, Lloyd Muccio, Ausbon Brown, and Brenda Smith, all of the NMFS Miami Laboratory, provided help with a variety of software questions. Jack Javech, also of the NMFS Miami Laboratory, helped update the statistical zone maps. Thanks also to Nancy Thompson of the NMFS Miami Laboratory who reviewed earlier drafts of this report and provided helpful comments and suggestions. Special thanks to Barbara Schroeder of the Florida DNR who answered many questions about the setup of the network and database.
